Notes: All models further control for age, sex, employment status, country, citizenship, membership of minority ethnic group, and ESS round.

Numbers (effects) in bold indicate significant effects ($p < 0.05$).

¹ The dependent variable SWB is a summative index based on happiness [“Taking all things together, how happy would you say you are?”] and life satisfaction [“All things considered, how satisfied are you with your life as a whole nowadays”].

² O pertains to parental educational attainment; D to own educational attainment.

³ Educational gradient estimated for non-mobile individuals; effects for reference group (low educated) are fixed at zero.

⁴ P-value of likelihood ratio test comparing Model 2 and Model 1.

Source: ESS4-7, own calculation.

Appendix 2: Main DMM analyses using a pooled sample

In addition to the stratified analyses, we estimated two nested DMM for the pooled sample of all 18 countries (see Table A.2). In line with our findings from the stratified analyses, the pooled model suggests that own education is relatively more important than parental education for young Europeans' life satisfaction. The education-based well-being gradient is substantial, the high educated having on average a 1.07 point higher life satisfaction score than their low educated counterparts. With regard to net mobility effects, model fit statistics indicate a better fit of model 2 as compared to model 1. We find statistically significant positive upward mobility effects and statistically significant downward mobility effects, *over and above* origin and destination effects.

Appendix 3: Effects of own and parental education (using linear regression)

As shown in Table 3 in the main text, DMM estimated origin weights that lie on the boundaries of the theoretically possible interval of 0.00 to 1.00 for the Nordic and Southern European countries. In other words, the estimates indicate that parental education has a zero well-being effect in these two country groups. To test the robustness of this finding, we ran conventional linear models regressing life satisfaction on own and parental education. These models corroborate the finding from DMM of very small and non-significant well-being effects of parental education for both country groups (see Table A.3).

Appendix 4: Overview of model fit – interaction effects

For a formal test of significance of differences in effects across country groups, we pooled all data from the 18 countries under investigation and tested interaction effects of our estimates for weights and diagonal effects with the country groups. We compared the fit of a series of nested models using likelihood ratio tests (see Table A.4). Model A, the baseline model, includes only the basic control variables (age, sex, ESS round, citizenship, minority group). Model B, additionally includes dummy variables for the country groups and shows a significantly better model fit. Model C allows control variables to vary across country groups, again significantly improving the model fit. Model D tests for significant differences between origin/destination weights across country groups. The significant improvement in model fit compared to model C suggests that the differences between country groups presented in this study are statistically significant. Model E additionally includes interaction effects between diagonal effects and country groups. The significant increase in model fit suggests significant differences in education-based well-being gradients across country groups. Given that model fit statistics suggest that model 2 shown in Table 3 (i.e., the model including mobility dummies) shows a significantly poorer fit to the data than model 1 in five out of six country groups, we refrain from carrying out a similar test of cross-country differences in net mobility effects.

Table A.4: *Overview of model fit – interaction effects*

Appendix 6: Main DMM analyses using a 4-category education variable

We conducted sensitivity analyses using a 4-category education variable instead of the 3-category version used in the main analyses (see Table A.6). We distinguish between basic education (less than lower secondary education comprising ES-ISCED level I), lower secondary education (ES-ISCED level II), higher secondary education (ES-ISCED levels IIIa, IIIb, and IV) and tertiary education (ES-ISCED levels V1 and V2). For the Nordic countries, the Visegrád Four, and the Baltic States, cell sizes for the lowest attainment level are, however, too small to allow for meaningful analysis (i.e., the number of respondents with only basic education is smaller than 25 in these country groups). Results for the three remaining country groups are found to be robust against this change in measurement.
